## **Arguments**

the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does

not contain an absolute path, the file name is relative to the current working directory, getwd(). Tilde-expansion is

performed where supported. This can be a compressed file (see file).

Alternatively, file can be a readable text-mode connection (which will be opened for reading if necessary, and if so closed (and hence destroyed) at the end of the function call). (If stdin() is used, the prompts for lines may be

somewhat confusing. Terminate input with a blank line or an EOF signal, Ctrl-D on Unix and Ctrl-Z on Windows.

Any pushback on stdin() will be cleared before return.)

file can also be a complete URL. (For the supported URL schemes, see the 'URLs' section of the help for url.)

header a logical value indicating whether the file contains the names of the variables as its first line. If missing, the value is

determined from the file format: header is set to TRUE if and only if the first row contains one fewer field than the

number of columns.

sep the field separator character. Values on each line of the file are separated by this character. If sep = "" (the default

for read.table) the separator is 'white space', that is one or more spaces, tabs, newlines or carriage returns.

quote the set of quoting characters. To disable quoting altogether, use quote = "". See  $\frac{\text{scan}}{\text{scan}}$  for the behaviour on quotes

embedded in quotes. Quoting is only considered for columns read as character, which is all of them unless

colClasses is specified.

dec the character used in the file for decimal points.
